Inside a Collapsing Bubble: Sonochemistry and Sonoluminescence

Kenneth S. Suslick
School of Chemical Sciences
University of Illinois at Urbana-Champaign

Fundamentally, chemistry is the interaction of energy and matter. Surprisingly, there are relatively few ways of putting energy into molecules. High intensity ultrasound has found numerous applications in driving chemical reactions and in the preparation of unusual materials, creating the field of sonochemistry. The chemical effects of ultrasound originate from acoustic cavitation: the formation, growth, and implosive collapse of bubbles in a liquid. From sonoluminescence spectroscopy, we have established that cavitation produces local conditions inside the bubbles of ~5000 K, ~1000 atm, with heating and cooling rates that exceed $10^{10}$ K/s. In isolated single bubbles, which can collapse more symmetrically and effectively, temperatures exceeding 20,000 K are observed.

In otherwise cold liquids, ultrasound is able to drive reactions that normally occur only under extreme conditions. The sonochemical syntheses of nanostructured metals, alloys, metal carbides, supported heterogeneous catalysts, and nano-colloids derives from the sonochemical decomposition of volatile organometallic precursors during cavitation, which produces clusters a few nm in diameter. Such nanostructured solids are active heterogeneous catalysts for various reactions. As examples, we have discovered a new synthesis of nanostructured MoS$_2$ and Mo$_2$C and of transition metal colloids of iron, cobalt, and iron-cobalt alloy colloids. Sonication of molybdenum hexacarbonyl in the presence of sulfur produces a novel morphology of MoS$_2$ with extremely high activity for catalytic hydrodesulfurization.

Another remarkable phenomenon occurs during ultrasonic irradiation of liquid-solid slurries: extremely high speed inter-particle collisions. Turbulent flow and shock waves produced by acoustic cavitation can drive metal particles together at sufficiently high velocities to induce melting upon collision. Metal particles that are irradiated in hydrocarbon liquids with ultrasound undergo collisions at roughly half the speed of sound and generate localized effective temperatures of ~3000 K at the point of impact. As a consequence, both stoichiometric and catalytic liquid-solid reactions can be tremendously enhanced. In addition, sonofragmentation of molecular crystals occurs readily, which greatly improves the uniformity of particles formed during crystallization, for example, of active pharmaceutical ingredients.

Kenneth S. Suslick is the Marvin T. Schmidt Research Professor of Chemistry at the University of Illinois at Urbana-Champaign. Professor Suslick received his B.S. from the California Institute of Technology in 1974 and his Ph.D. from Stanford University in 1978, and came to the University of Illinois immediately thereafter. He is the recipient of the Centenary Prize and the Sir George Stokes Medal of the RSC, the MRS Medal, the ACS Nobel Laureate Signature Award for Graduate Education, the ACS Senior Cope Scholar Award, a Guggenheim Fellowship, an NIH Research Career Development Award, a Sloan Foundation Research Fellowship, and the Silver Medal of the Royal Society for Arts, Manufactures, and Commerce; he is a Fellow of the AAAS, ACS, RSC, MRS, APS, and the Acoust. Soc. Amer. He has published more than 360 papers, edited four books, and holds 42 patents and patent applications.
